

# SILENT CAPTURED SPRING SELECTION GUIDE

**JPSCS2-15**

**JPSCS2-10**

**JPSCS2-9MM**

**JPSCS2-9MM-5H2**

Ver. 05.17

This guide is intended to answer any questions about compatibility issues with the GEN 2 Silent Captured Spring System as well as help you determine which SCS unit is appropriate for your rifle.

This guide applies only to gas guns. For 9mm blowback systems, the JPSCS-9MM is the appropriate choice. To check compatibility with a particular 9mm system, refer to the System Compatibility section of this guide, which is universal for all SCS models, including the JPSCS2-9MM.

## **CONTENTS**

- I System Compatibility**
- II SCS2-15 or SCS2-10?**
- III Standard or Heavy SCS?**
- IV 9mm SCS Selection**
- V Compatibility Modifications**

# I SYSTEM COMPATIBILITY

The Silent Captured Spring System requires four dimensional compatibilities.

## 1: Bolt Carrier Channel: Minimum .530" bore

The guide rod of the Silent Captured Spring passes into the bolt carrier during cycling and must have adequate clearance. The Mil-spec bore for a bolt carrier is .625", and this is not a problem for most carriers. The only incompatibilities found to date are with Primary Weapon Systems carriers and certain 9mm bolt assemblies. Some 9mm bolts have a removable mass, which will allow function with the 9mm SCS.

## 2: Bolt Carrier Channel: Minimum 3.75" depth

During cycling, the guide rod must be able to pass far enough into the bolt carrier without bottoming out on the rear of the firing pin.

The SCS2-15 requires a minimum depth of 3.75" which can be a problem with the HK 416 platform. The SCS2-10 requires a minimum depth of 4.4" which is incompatible with the DPMS GII, Remington R-25 GII and certain other rifles.

**Workaround:** For a rifle-length system, the included spacer can be modified to allow function. This involves opening up the central channel to accommodate the SCS guide rod and placing the spacer in front of the SCS in the buffer tube. See the Compatibility Modifications section.

## 3: Buffer Tube: Standard rifle, M4 carbine or pistol, DPMS .308 carbine (or something in between)

By itself, a Silent Captured Spring will fit a standard M4 carbine-length buffer tube (as well as an AR pistol buffer tube) or a DPMS .308 carbine-length buffer tube. With the included spacer, an SCS unit will fit exactly to a rifle-length buffer tube.

Many .308s are now using a mid-length buffer tube that is around 7¾" long, which is not compatible with the SCS "out of the box."

**Workaround:** The included spacer can be shortened to accommodate a buffer tube length somewhere between rifle and carbine. See the Compatibility Modifications section.

## 4: Bolt Stroke: Non-standard

Certain platforms such as the Rock River Arms LAR-8 and certain older model Bushmasters have a longer than normal bolt stroke. Because of this, the Silent Captured Spring unit will bottom out and not cycle the system properly.

## II SCS2-15 or SCS2-10?

The JPSCS2-15 (as well as JPSCS2-15H2) is intended for use with small-frame rifles while the JPSCS2-10 (and JPSCS2-10H2) are for use with large-frame rifles.

**Small-frame rifles** are often referred to as AR-15s and are the semi-automatic equivalent of the M16. These rifles are completely or semi-Mil-spec compatible. They are most commonly chambered in .223 / 5.56 NATO, though numerous other chamberings are common, including .204 Ruger, 6.5 Grendel and .300 AAC Blackout.

**Large-frame rifles** are scaled up versions of the AR-15, usually built upon the DPMS LR-308 or Armalite AR-10 patterns of receivers and components. These rifles are most commonly chambered in .308 / 7.62 NATO but can also be configured for any of the following:

- **.243 Winchester**
- **.260 Remington**
- **6.5 Creedmoor**
- **7mm-08 Remington**
- **.338 Federal**
- **.358 Winchester**
- **.45 RAPTOR**

## III STANDARD or HEAVY SCS?

The extra weight of the heavy version Silent Captured Spring translates into more reciprocating mass (i.e., deadblow effect) against the carrier, which aids reliability. While this enlarges the rifle's operational window, it will not lessen the movement impulse as much.

The standard SCS2-15 has more buffering potential than a standard carbine buffer and roughly equal total mass. The standard AR-10 SCS2-10 model is a LMOST™ (Low Mass Operating System) component meant to run best with a low-mass carrier like our JPBC-4.

These standard models will yield dramatic performance improvements, but on some particular setups, they may lead to occasional failures such as the carrier not always going into battery.

Rifle configuration plays a larger role than caliber. That said, we generally recommend the H2 SCS for small-frame rifles in calibers larger than .223 / 5.56 unless the rifle is biased toward low mass operation.

The masses of the SCS2 models have been calibrated to correspond to standard H, H2, and H3 buffer weights for both the AR-15 and AR-10 models:

<u>Mass Configuration</u>	<u>Buffer Equivalent</u>
2 Steel, 1 Tungsten	H
1 Steel, 2 Tungsten	H2
3 Tungsten	H3

If you have an adjustable gas system, most any rifle can be made to function with either the standard or heavy SCS so long as it isn't:

- **an SBR**
- **full-auto**
- **suppressed**
- **piston-operated**

Refer to the flow chart on the next page to determine which of our SCS preconfigurations is best suited to your rifle.

## IV 9MM SCS SELECTION

Two versions of the 9mm Silent Captured Spring are available from JP Enterprises to accommodate different pistol-caliber carbine configurations and ammunition choices. While both versions are largely interchangeable in terms of basic function, the Enhanced Version (**JPSCS2-9MM-5H2**) will provide superior function than the standard version (**JPSCS2-9MM**) under more taxing circumstances.

The Enhanced Version 9mm Silent Captured Spring uses a five-mass slider as opposed to the four-mass slider of the standard version. While the buffering mass of the two versions remains nearly the same (as normally configured), the overall bolt mass of the Enhanced Version is increased by 2.25 oz. This extra weight softens recoil even further by delaying the blow back of the operating system. The five-mass slider of the Enhanced Version also allows more possible mass configurations.

The Enhanced Version is recommended for shooters with the following:

### **Hotter Ammunition**

The steel slider of the Enhanced Version (as opposed to the standard aluminum) is more durable, and the use of a shorter bumper will reduce the deformation that occurs due to the higher-energy impact of hotter loads. The extra mass of the slider also increases lock time, reducing the possibility of case rupture.

### **9mm Bolts With Masses Removed**

The central mass slug of some manufacturers' 9mm bolts must be removed to allow the Silent Captured Spring to function properly. This represents a reduction in the overall mass of the operating system. While the standard 9mm SCS can offset much of this loss, the Enhanced Version offers a wider range of mass adjustment to ensure reliable function.

## V COMPATIBILITY MODIFICATIONS

This section details the modifications that can be made to the Silent Captured Spring to allow its use for certain applications or improve/optimize its function.

### Changing Springs

Alternate spring packs are available for both the SCS-15s and SCS-10s. By switching to a heavier or lighter spring, you can optimize the cycling of your particular rifle. Further details and complete instructions can be found on our website. Before disassembly, note that the SCS screws are metric and require a 3mm hex key.

### Changing Masses

The standard SCS units use steel masses while the heavy H2 versions use a combination of steel and tungsten masses. The number of tungsten weights corresponds to the standard buffer weight (H, H2, H3). See the table in Part III.

Any unit can be disassembled and the weights exchanged. Further details and complete instructions can be found on our website.

### Boring the Spacer for Positioning in Front of SCS

Positioning the spacer in front of the SCS can compensate for restricted bolt carrier bore dimensions. To modify the SCS spacer for this use requires both opening up the central bore and planing the sides of the spacer to avoid hydraulic lockup.

Use of a lathe or mill is preferable for these modifications, but standard tools will suffice. Using a suitable drill bit, open up the central channel to .5 inches as shown. Creating the flats on the side

can be accomplished with a sander or grinding wheel, but make only brief contact as the plastic of the spacer will quickly begin to melt.

If you prefer not to perform this modification yourself, contact us to obtain a modified spacer for a nominal price.

### Shortening the Spacer

To accommodate a buffer tube shorter than a full-length rifle tube but longer than a carbine, the SCS spacer can be shortened. This modification should only be done on a lathe or other suitable machine to ensure a precisely level surface. If the spacer is cut unevenly, the SCS will not sit flush and may wear unevenly.

The easy alternative to modifying the spacer is to simply use suitably sized plastic washers to bridge the gap. These can be found easily online or at your hardware store.
